## Error in Eulers Method

Examine the error for the solutions that we found in the last class:

$$\frac{dy}{dx} = e^{x^2} \quad y(0) = 1$$

1. How much were we reducing  $h$  each time? What do you expect your ratio of errors to be based on how you are reducing  $h$ ?
2. Calculate the approximate error by subtracting the approximations - you can use the numbers you wrote into the last worksheet, or use the Python code I provided. Fill in the table below. Recall that

$$ERROR \sim |y_h - y_{\frac{h}{10}}|$$

| $h$   | Error in $y(1)$ | Ratio of errors |
|-------|-----------------|-----------------|
| .1    | ----            | ----            |
| .01   |                 | ----            |
| .001  |                 |                 |
| .0001 |                 |                 |
| ...   |                 |                 |

Here I am only asking for the approximate error because we don't know the real solution.

3. Answer the following questions:

- Did your ratio of errors reduce as expected?
- Is your approximation converging to a solution?
- For the largest  $h$  value that you calculated, about how many decimal places of accuracy do you have?

## Repeat the steps 1-4

$$y' = x^2 - y^2 \quad y(0) = 1$$

| $h$   | Error in $y(1)$ | Ratio of errors |
|-------|-----------------|-----------------|
| .1    | ----            | ----            |
| .01   |                 | ----            |
| .001  |                 |                 |
| .0001 |                 |                 |
| ...   |                 |                 |
